

The K-dependence of the surprise threshold, and its fix

With a fixed θ the floor of $\bar{A}$ rises with K (0.350 $\rightarrow$ 0.399 $\rightarrow$ 0.440 $\rightarrow$ 0.468), so $\theta = 0.5$ sits at 3.8σ / 2.3σ / 1.3σ / 0.7σ above it — conservative in one regime, buried in the noise in another. The network

A · The optimal threshold shifts with K

B · Where the network places it by itself

C · Gain over the paper's value
